Background
Urinary tract infection (UTI), the most common infection of the urogenital system, is regarded as one of the most frequent infections in childhood (1). It can occur in two forms, namely, cystitis and acute pyelonephritis (APN). Delay in treating the acute infection can lead to injury to the renal parenchyma, which is also called renal scarring (2, 3). With incidence rates ranging from 5 to 57% following APN, renal scarring can result in progressive kidney damage (4).

Objectives
Thus, this study aimed to evaluate the role of vitamin A in the prevention of renal parenchymal injury in children with acute pyelonephritis.

Methods
Participants
The current assessor-blind randomized controlled trial included 108 children with suspected APN (based on clinical findings and positive urine culture) aged three months to 14 years, who were admitted to Bandar Abbas Children's Hospital, Bandar Abbas, Iran, in 2020. Patients were randomly allocated to two equal groups. Children in the vitamin A group received vitamin A in addition to antibiotics (ceftriaxone), while those in the control group only received antibiotics. Then, children in both groups underwent dimercaptosuccinic acid (DMSA) scanning once at baseline and four months after treatment. Photopenic areas in the DMSA scan were regarded as damaged areas. Further, serum vitamin A levels, C-reactive protein (CRP) levels, and erythrocyte sedimentation rate (ESR) were measured in all participants before the initiation of treatment. Finally, the demographic features of the participants were noted, including age and gender.

Results
Patients in both groups were comparable regarding age and sex. Serum vitamin A levels, CRP, and ESR did not differ significantly between groups before treatment. The mean number of photopenic areas in the baseline DMSA scan was similar in both groups (P = 0.481); however, the mean number of photopenic areas in the DMSA scan after four months was significantly lower in the vitamin A group compared to controls (P = 0.004).

Conclusion
Therefore, the use of vitamin A, along with antibiotics can significantly decrease renal damage in children with APN.

months to 14 years admitted to Bandar Abbas Children’s Hospital, Bandar Abbas, Iran from January 1, 2020, to September 20, 2020. The inclusion criterion was positive culture (≥10⁵ CFU/mL in bagged specimens, ≥10⁴ CFU/mL in catheterized specimens, or ≥10² CFU/mL in suprapubic aspirations). Patients who had anatomical disorders of the urinary system were excluded from the study. The sample size was calculated as at least 108 participants based on α = 0.05, and β = 0.1.

**Study Design**

First, written informed consent was obtained from the parents or guardians of the children. The age and sex of the participants were recorded as well. A random venous blood sample was collected from all the children before treatment for the measurement of serum vitamin A, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). Serum vitamin A was measured using the high-performance liquid chromatography method (Younglin device, Korea).

Patients were randomly assigned to two equal groups (54 in the vitamin A group and 54 as controls) using simple randomization by randomly generated numbers produced by the Random Allocation software. Details of patient enrollment, randomization, and analysis are depicted in Figure 1. Children in both groups received 50-75 mg/kg of intravenous ceftriaxone daily. In addition to ceftriaxone, children in the vitamin A group received 25000 and 50000 units of intramuscular vitamin A (Osvah Pharmaceutical Co., Iran) if they were younger than 1 year and ≥1 year on their first day of admission, respectively. Children in both groups received 8 mg/kg oral cefixime daily after discharge.

All children underwent dimercaptosuccinic acid (DMSA) scanning using the Siemens E.Cam® single-head scanner once before treatment and four months after treatment. DMSA scans were evaluated by an experienced pediatric nephrologist who was blinded to the grouping of patients. Photopenic areas in the DMSA scan were regarded as damaged areas.

**Data Analysis**

The Statistical Package for the Social Sciences (SPSS) software (version 26.0, Armonk, NY: IBM Corp., USA) was used for data analysis. Mean, standard deviation, frequency, and percentages were applied to describe the variables. Based on the results of the Kolmogorov-Smirnov test, continuous and categorical variables were compared between groups using the Mann-Whitney and chi-square tests, respectively. Further, the Wilcoxon test...
was employed to compare the mean number of photopenic areas on DMSA scans before and after treatment, and *P* values ≤0.05 were considered statistically significant.

**Results**

Of the 108 children included in this study with a mean age of 5.63 ± 2.24 years, 52 (48.1%) were boys and the remaining 56 (51.9%) were girls. Table 1 presents the comparison of demographic features between groups. Children in the vitamin A and control groups were comparable in terms of age (*P* = 0.914) and sex (*P* = 1.000).

Baseline serum vitamin A levels, CRP, and ESR did not differ significantly between groups (*P* = 0.152, *P* = 0.064, and *P* = 0.393, respectively, Table 2). Likewise, there was no statistically significant difference between the vitamin A and control groups regarding the mean number of photopenic areas in the baseline DMSA scan (*P* = 0.481). The mean number of photopenic areas significantly decreased in both groups in the follow-up DMSA; however, this reduction was higher in the vitamin A group (Table 3). Figures 2 and 3 demonstrate the number of photopenic areas in the baseline and follow-up DMSA scans in both groups.

**Discussion**

In the current study, it was found that vitamin A can reduce renal scarring in children with APN. The follow-up DMSA scan, performed four months after treatment, showed a significantly lower number of photopenic areas in the vitamin A group compared to controls, which is in line with the results of Kahbazi et al. They evaluated the efficacy of vitamin A plus antibiotics for the improvement of UTI symptoms and prevention of renal scarring in girls with APN. In their study, the worsening of renal lesions in the second DMSA scan was significantly lower with vitamin A compared to placebo. Further, 63.8% of the patients in the vitamin A group had improvements in the number of photopenic areas, while the corresponding percentage in the placebo group was 21% (4). Similarly, Zhang et al concluded that vitamin A is inversely correlated with renal parenchymal injury (7). On the other hand, the findings of Dalirani et al are consistent with those of our study. They investigated the role of vitamin A in the prevention of renal scars following APN and reported significantly lower progression of renal damage and scars in the vitamin A group in comparison with controls (12). Moreover, Ayazi et al demonstrated significantly lower permanent renal damage with vitamin

A (13). The results of Yilmaz et al are also in conformity with our findings (14).

Although Sobouti et al compared vitamin A and E supplementation for the reduction of renal scars secondary to APN and found comparable results with both vitamins, the effect of vitamin E was more promising compared to vitamin A (15). This indicates that in future studies, other vitamins should be compared with vitamin A for the prevention of renal scarring in APN. Yousefichaijan et al evaluated the effect of vitamin A on the clinical presentations of recurrent APN in children. Although they did not study renal parenchymal damage, they reported that vitamin A administration led to a significant decrease in urinary symptoms and fever. Additionally, they concluded that vitamin A can be used for the treatment of children with APN (2).

In general, the results of a limited number of studies evaluating the role of vitamin A in APN conform to and confirm our results. Therefore, it appears that vitamin A is beneficial for the prevention of renal scars in children with APN or the reduction of the already-formed scars in the acute phase of the infection. Of note, the strength of the current study, compared to previous studies, was that both groups of our study were comparable regarding the demographic features, as well as baseline serum vitamin A levels, CRP, and ESR, which limits the potential confounding effects of these factors on the results.

Nonetheless, this study was not without limitations. The sample size was relatively small, which can restrict the generalizability of our findings. Future studies with a larger sample size are required to confirm our results.

Conclusion
In the current study, vitamin A was effective for the prevention of renal scarring in children with APN. Thus, we recommend the administration of a single dose of intramuscular vitamin A in children with APN to avoid or reduce the severity of renal scarring.

Acknowledgments
We would like to express our sincere gratitude toward the investigators, coordinators, volunteer patients and their parents/guardians, and the personnel of Bandar Abbas Children’s Hospital, Hormozgan, Iran.

Authors’ Contribution
Conceptualization and study validation: KG. Study supervision: ME. Implementation: SMAK. Data analysis and interpretation: SMAK. Writing and reviewing: KG. All the authors have read and approved the manuscript.

Availability of Data and Materials
The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Conflict of Interests
The authors declare that they have no competing interests.

Ethics Approval
The study received ethics approval from the Ethics Committee of Hormozgan University of Medical Sciences (ethics code: IR.HUMS.REC.1399.313) and it complies with the statements of the Declaration of Helsinki. Written informed consent was obtained from the parents/guardians of the participants.

Funding/Support
The study was financially supported by Hormozgan University of Medical Sciences.
